

Build it - as an institutional alpha research operating system

01

Final recommendation distilled into the decisions, controls and outcomes that matter

DECISION

Approve V1, with three non-negotiable upgrades.

The proposed design is fundamentally correct: AI should interpret research and generate only small, auditable signal logic; deterministic infrastructure should own data, execution, costs, portfolio construction and measurement. The investment edge will come from data integrity, signal differentiation and disciplined promotion - not from maximizing the number of backtests.

Why this should be built

- Structured Strategy Cards expose ambiguity before code is run.
- Template-constrained generation sharply reduces implementation risk.
- Two short human gates control interpretation and investment judgment.
- A persistent research library compounds institutional knowledge.

What must change

- Make point-in-time lineage and frozen data snapshots mandatory.
- Separate paper replication from India investability validation.
- Fingerprint signals and expose factor, sector and liquidity bets.
- Replace promising/rejected with a governed promotion ladder.

How success is measured

- Screen 20 papers a day; investigate only genuinely distinct ideas.
- Promote on incremental IR, turnover, CVaR, liquidity and capacity.
- Target one differentiated portfolio-useful signal every few weeks.
- Treat negative results and failed replications as reusable knowledge.

NORTH STAR

20 papers screened / day → 3-5 distinct ideas investigated → 1 portfolio-useful signal / few weeks

Throughput is an operating metric. Orthogonal, implementable alpha is the outcome.

REQUIRED INVESTMENT GATES

Each promotion stores the dataset snapshot, source dates, code hash, model version, overrides, evidence and reviewer sign-off.

End-to-end research-to-deployment architecture

AI interprets. Deterministic systems compute. Humans govern. The research graph compounds knowledge.
